

# Small inversions for smaller inversions

Jean-François Monin

## Abstract

We describe recent improvements on *small inversions*, a technique presented earlier as a possible alternative to Coq standard inversion.

Many proofs relying on inductive definitions require so-called *inversion* steps in order to exploit the information contained in a hypothesis  $H : Ra_0 \dots a_n$ , where  $R$  is a dependent inductive relation (or type) applied to actual parameters  $a_0 \dots a_n$ . In Coq, such steps are usually performed using a powerful tactic called `inversion`. In previous work [MS13], we proposed an alternative lightweight approach, which is not automated (in contrast with Coq `inversion`) but provides a better understanding on what happens, a full control on the proof script and smaller proof terms. In particular, no additional (proof of) equalities are introduced. Moreover, there are situations involving dependent types where standard `inversion` fails whereas small inversion succeeds. In all approaches, inversion is essentially a complex dependent pattern matching on  $H$ . In [MS13], this is handled using auxiliary functions.

However, we discovered later that standard `inversion` has an additional important advantage on the previous version of small inversions: it provides syntactically strict subterms of  $H$  which can directly be used in recursive calls of a fixpoint definition. In the Braga method designed with D. Larchey-Wendling [LWM18, LM21], we showed how clear and explicit subterms of  $H$  can be recovered using projections  $\pi_R$  defined with a dependent pattern matching similar to small inversions – let us call them *smaller inversions*.

We present here an improvement on small inversions, where auxiliary functions are replaced with auxiliary inductive types which are easier to understand and to use. The new small inversion is more powerful: it can handle goals involving terms with occurrences of  $H$ . Such goals naturally arise in direct proofs of partial correctness properties of functions – for instance, but not only, fixpoints obtained by the Braga method. Standard `inversion` turns out to be very often unusable there.

As a foretaste, consider a *reference* function for OCaml `fold_left` – efficiency is then irrelevant here – honestly defined by a right to left traversal of its list argument. To this effect we introduce an auxiliary *non-recursive* dependent data type `rl l` with two constructors: `Nilr` of type `rl []` – reflecting the empty list – and `Consr` of type `rl (u + : z)` – where  $u + : z$  is the catenation of a list  $u$  and a single element  $z$ . Following the Braga method, we first define an inductive domain  $D_{list}$  for termination certificates. Here  $D_{list}$  contains `Nilr`, as well as `Consr u z` whenever `l2r u`, the reflection of  $u$ , is itself in  $D_{list}$ . Given  $d : D_{list}$  (`Consr u z`) we then define the projection  $\pi d$  which provides its structurally smaller component of type  $D_{list}$  (`l2r u`), allowing us to easily define fixpoints such as `foldl_ref` below, where  $b_0$  and  $f$  are respectively an initial value and a function to be folded, and `rew d` is an administrative rewriting step transforming `l2r (u + : z)` into `Consr u z`.

```
Fixpoint foldl_ref l (d: Dlist (l2r l)): B :=
  match l2r l in rl l return Dlist (l2r l) → B with
  | Nilr      => λ d, b0
  | Consr u z => λ d, f (foldl_ref u (π (rew d))) z
end d.
```

Reasoning on such functions commonly requires inversion steps on  $d$ . For instance we would like to prove that the actual standard tail-recursive algorithm returns the same result as

`foldl_ref`. But we already get an issue with a much more elementary fact, stating that for any  $d : D_{list} \text{ Nilr}$ , we have `foldl_ref [] d = b0`: this turns out to be out of reach of Coq standard inversion. In [LM21], this issue is circumvented by replacing the former definition of `foldl_ref` by an enriched program which returns an inhabitant of  $\{b : B \mid G_{foldl} l b\}$  instead of just  $B$ , where  $G_{foldl}$  is a suitable characteristic relation. With our small inversion described below, we can directly reason on `foldl_ref` as defined above. More details and additional examples are available at [https://www-verimag.imag.fr/~monin/Proof/Small\\_inversions/2022](https://www-verimag.imag.fr/~monin/Proof/Small_inversions/2022).

For a more general situation, consider an inductive relation  $R : T_0 \rightarrow T_1 \dots \rightarrow T_n \rightarrow \text{Sort}$ , where  $\text{Sort}$  is a sort (e.g., `Prop` or `Type`). Whatever the technology to be used, the key point is that inversion makes sense when:

- at least one type among  $T_0, T_1 \dots T_n$ , say  $T_0$ , is itself an inductive type; without loss of generality we consider here that there is exactly one such type; below we write  $\mathbf{T}$  for  $T_1 \dots T_n$ ;
- in the hypothesis  $H$  to be inverted, the corresponding actual parameter  $a_0 : T_0$  has a specialized shape  $\sigma$ , corresponding to a pattern  $C \text{ args}$  starting with a constructor  $C$  of  $T_0$  (in many cases,  $\text{args}$  are just variables).

In general, only a subset of the constructors of  $R$  are compatible with the shape of  $a_0$ . Inversion then proceeds by *simultaneous* pattern-matching on  $H$  and  $a_0$ , in order to select the relevant cases of  $R$ .

We proceed as follows. For each shape of interest  $\sigma$  we derive from the definition of  $T_0$  an inductive specialized version  $T_{0\sigma}$  of  $T_0$ .  $T_{0\sigma}$  is a copy-paste of the relevant (compatible with  $\sigma$ ) constructors of  $T_0$ , with appropriate modifications: the variables  $x_1 \dots x_\sigma$  of  $\sigma$  become parameters of  $T_{0\sigma}$ ; the type of  $T_{0\sigma} x_1 \dots x_\sigma$  is  $\forall \mathbf{a} : \mathbf{T}, R \sigma \mathbf{a} \rightarrow \text{Sort}$  (it is empty for absurd cases). We then define, by dependent pattern matching on  $r$ , the function  $R_{inv} y_0 \mathbf{y}$  of type  $\forall r : R y_0 \mathbf{y}, (\text{match } y_0 \text{ with } \dots \mid \sigma_i \Rightarrow T_{0\sigma_i} x_1 \dots x_{\sigma_i} \mid \dots \text{end}) r$ .

The main argument of  $R_{inv}$  is  $r$  (its other arguments  $y_0 \mathbf{y}$  will be left implicit). An obvious requirement on the shapes  $\sigma_i$  occurring in the above pattern matching is that they cover  $T_0$ . Inverting  $H$  is then just a pattern matching on  $R_{inv} H$ , whose type reduces to the relevant  $T_{0\sigma_i}$ . Possible occurrences of  $H$  in the goal are correctly dealt with for free thanks to the additional argument  $r$  of  $T_{0\sigma}$ .

In this version, the components of  $H$  are not considered as subterms of  $H$  because they are repackaged in a constructor of  $T_{0\sigma}$ . In the Braga method, where the subterm property is needed, an argument of type  $R y_0 \mathbf{y}$  can be added to  $T_{0\sigma}$  and its final argument uses of  $\pi_R \sigma$  instead of  $\sigma$ . Even if the sort of  $T_0$  is `Prop`, we can then obtain a fully general recursion principle `T0_rect` – an improvement on [LM21] which is limited to proof irrelevant statements.
